Lab 1: Measuring the Real World<br>Math/CS-484: F/K - Visualizing Scientific Data<br>Leif DeJong

Model: The model to be built is measuring a 2D enclosed space in order to calculate its area. Several measuring tools will be used in order to demonstrate the variety of results from this methodology.

Process: The process is broken up into stages. The first stage involves collecting data of the enclosed area. The second stage involves post processing the raw data, and the third stage involves visualizing the data.

Assumptions: The enclosed area is a rectangle, the enclosed area is flat, the sidewalks are straight, and the corners of the sides are a $90^{\circ}$ angle

## Collecting Data:

Method 1 - "The Shoe": This method involves walking around the parameter of the enclosed area heel to toe keeping count of every side. This is repeated three times whereafter the shoe will be measured and the total steps multiplied to the length of the shoe.

Method 2 - "Large Wheel": Using the large measuring wheel, walk around the parameter of the enclosed area taking note of the length of each side. This is to be repeated three times.

Method 3 - "Small Wheel": Using the small measuring wheel, walk around the parameter of the enclosed area taking note of the length of each side. This is to be repeated three times.

## Post Processing the Raw Data:

Step 1: Convert from feet to meters using Google's Unit Converter keeping precision to a max.

Step 2: Average the "Short Sides": Take the average values of the Bundy Side and Heart Side to acquire a measurement for the short side of the rectangle.

Step 3: Average the "Long Sides": Take the average values of the Barrette Side and Tyler Hall Side to acquire a measurement for the long side of the rectangle.

Step 4: Find the Area: Multiply the values for the short and long side together to get the area of the rectangle. Make sure that the units are meters squared and the precision is two.

Method 4 - "Tape Measure": Using the tape measure, have a partner on one end of the four sides and walk along a side until you reach the end whereafter you take the reading, roll up the tape, and then start over except with another side of the enclosed area. This is to be repeated three times.

Method 5 - "Google Planimeter": Using Google's planimeter software based on Google's Maps, take three readings to the enclosed space's area. ${ }^{1}$

Method 6 - 'Planimeter": Using Charlie Peck's Planimeter, take a map of campus, set the scale to the planimeter, take the measurement, do the correct math, and record your results three times. Convert the units from $\mathrm{ft}^{2}$ to $\mathrm{m}^{2}$.

## Visualizing the Data:

For the scope of this project, I found it appropriate to use a bar graph to visualize the data. It allows me to have a flat view of all the data and the arithmetic mean.

What makes good visualizations is being able to present the scope of your data and having it be analyzed without biasing it.

## There are two Visualizations:

1) Has the 5 first measurement methods
2) Has all 6 measurement methods

Visualization 2: All Methods

Trial 1
Trial 2
Trial 3
Mean

General: The irregularity of the sidewalks along with objects protruding or intruding may have caused some error with some of the measurement devices. Our assumptions about the experiment also lead to a conceivable amount of error along with improper use of some of the tools when trying to make accurate measurements. Like any experiment, it is subject to a certain amount of human error.

Shoe: After spending 45 minutes walking around the enclosed area, sources of error include potentially losing count especially on "Trial 3 " and not having the exact step every iteration of the process.

Small and Large Wheel: This measurement tool often oscillated horizontally which could lead to a source of error. The wheels were subject to slipping or being interrupted by the condition of the sidewalk.

Tape Measure: When I did the measurement, I moved the tape, rippled it, tugged it, and remeasured. This may be the explanation why the measurements are very close and create this misguided assumption of the actual area.

G-Planimeter: I do not know exactly how the software was engineered and therefore have to assume that there is a certain amount of error involved with the methodology.

Planimeter: I have a feeling by looking at the results that there was a lot of error with the operation of this device. This could also be error in the actual map or the precision at which it was measured.

Absolute and Relative Error: Included in the "Totals and Error" table below.
